AXIOMAS DE ARMSTRONG

The term Armstrong Axioms refers to the sound and complete set of inference rules or axioms, introduced by William W. Armstrong, that is used to test the logical implication of functional dependencies [1]. Armstrong Axioms are a set of references (or, more precisely, inference rules) for inferring all of a relational database's functional dependencies [2].

If F is a set of functional dependencies then the closure of F , denoted as F^+ , is the set of all functional dependencies logically implied by F

$$F^+ \rightarrow \{ \dots \}$$

AXIOMS

- **Axiom of Reflexivity:**

If A is a set of attributes and B is a subset of A , then A holds B . If $B \subseteq A$ then $A \rightarrow B$. This property is trivial property[1].

$$\text{if } B \subseteq A$$

$$A \rightarrow B$$

Example: A university student profile contains attributes: $\{Student_ID, Name, Major\}$.

- Since $\{Student_ID, Name\}$ is a subset of $\{Student_ID, Name, Major\}$, we can say:

$$\{StudentID, Name, Major\} \rightarrow \{Name\}$$

- This means that if we know all three attributes, we automatically know "Name," which is trivial [3].

- **Axiom of Augmentation:**

If $A \rightarrow B$ holds and Y is the attribute set, then $AY \rightarrow BY$ also holds. That is adding attributes to dependencies, does not change the basic dependencies. If $A \rightarrow B$, then $AC \rightarrow BC$ for any C [1].

$$\text{if } A \rightarrow B$$

$$AC \rightarrow BC$$

Example: Consider an employee database where:

- $\text{Employee_ID} \rightarrow \text{Employee_Name}$ (An employee ID determines their name).
- If we introduce another attribute, "Department," the dependency still holds:
 $\{\text{EmployeeID}, \text{Department}\} \rightarrow \{\text{EmployeeName}, \text{Department}\}$
- Adding "Department" doesn't affect the basic dependency [3].

- **Axiom of Transitivity:**

Same as the transitive rule in algebra, if $A \rightarrow B$ holds and $B \rightarrow C$ holds, then $A \rightarrow C$ also holds. $A \rightarrow B$ is called A functionally which determines B. If $X \rightarrow Y$ and $Y \rightarrow Z$, then $X \rightarrow Z$ [1].

$$\text{If } X \rightarrow Y \text{ and } Y \rightarrow Z$$

$$X \rightarrow Z$$

Example: In an airline booking system:

- $\text{Passenger_ID} \rightarrow \text{Seat_Number}$ (A passenger ID determines a seat number).
- $\text{Seat_Number} \rightarrow \text{Flight_Number}$ (A seat number is associated with a flight).
- Therefore, $\text{Passenger_ID} \rightarrow \text{Flight_Number}$ (A passenger ID ultimately determines the flight they are on) [3].

SECONDARY RULES

- **Union:**

If $A \rightarrow B$ holds and $A \rightarrow C$ holds, then $A \rightarrow BC$ holds. If $X \rightarrow Y$ and $X \rightarrow Z$ then $X \rightarrow YZ$ [1].

Example: In an online shopping system:

- $\text{Order_ID} \rightarrow \text{Customer_ID}$ (An order ID determines the customer).
- $\text{Order_ID} \rightarrow \text{Order_Date}$ (An order ID also determines the order date).
- So, $\text{Order_ID} \rightarrow \{\text{Customer_ID}, \text{Order_Date}\}$ (An order ID determines both customer and order date) [3].

- **Composition:**

If $A \rightarrow B$ and $X \rightarrow Y$ hold, then $AX \rightarrow BY$ holds [1].

Example: In a university system:

- $\text{Student_ID} \rightarrow \text{Student_Name}$ (A student ID determines their name).
- $\text{Course_Code} \rightarrow \text{Course_Title}$ (A course code determines the course title).
- So, $\{\text{Student_ID}, \text{Course_Code}\} \rightarrow \{\text{Student_Name}, \text{Course_Title}\}$ (A combination of student ID and course code determines both student name and course title) [3].

- **Decomposition:**

If $A \rightarrow BC$ holds then $A \rightarrow B$ and $A \rightarrow C$ hold. If $X \rightarrow YZ$ then $X \rightarrow Y$ and $X \rightarrow Z$ [1].

Example: In a vehicle registration system:

- $\text{License_Plate} \rightarrow \{\text{Car_Model}, \text{Car_Owner}\}$ (A license plate determines both the car model and owner).
- By decomposition:

$$\text{LicensePlate} \rightarrow \text{CarModelLicense}_{\text{plate}}$$

$$\text{LicensePlate} \rightarrow \text{CarOwnerLicense}_{\text{plate}}$$

- Each piece of information can be determined separately [3].

- **Pseudo Transitivity:**

If $A \rightarrow B$ holds and $BC \rightarrow D$ holds, then $AC \rightarrow D$ holds. If $X \rightarrow Y$ and $YZ \rightarrow W$ then $XZ \rightarrow W$ [1].

Example: In an HR system

- $\text{Employee_ID} \rightarrow \text{Department}$ (An employee ID determines the department).
- $\{\text{Department}, \text{Manager_ID}\} \rightarrow \text{Budget}$ (A department and manager together determine the budget).
- Therefore, $\{\text{Employee_ID}, \text{Manager_ID}\} \rightarrow \text{Budget}$ (An employee ID and manager ID together determine the budget) [3].

- **Self Determination:**

It is similar to the Axiom of Reflexivity, i.e. $A \rightarrow A$ for any A [1].

Example: This is trivial in any system. For example, a Social Security Number (SSN) determines itself [3]:

$$SSN \rightarrow SSN$$

- **Extensivity:**

Extensivity is a case of augmentation. If $AC \rightarrow A$, and $A \rightarrow B$, then $AC \rightarrow B$. Similarly, $AC \rightarrow ABC$ and $ABC \rightarrow BC$. This leads to $AC \rightarrow BC$ [1].

Example: In an academic grading system:

- $\{\text{Exam_ID}, \text{Student_ID}\} \rightarrow \text{Exam_ID}$ (Knowing both doesn't change that we know the exam ID).
- $\text{Exam_ID} \rightarrow \text{Exam_Schedule}$ (An exam ID determines the schedule).
- By extensivity: $\{\text{Exam_ID}, \text{Student_ID}\} \rightarrow \text{Exam_Schedule}$ (Knowing both still determines the exam schedule) [3].
